SAP Web Components

Intro

The page is a container component for a full application screen comprising a header, content area, and footer.

Demo Page

A page is a single, self-contained unit of information that is presented to users within a website or application. It typically consists of a layout, content, and interactive elements such as buttons, links, and forms.

When using a page, it is important to ensure that the content is clear and organized in a way that makes it easy for users to understand and navigate. This can be achieved by using a consistent layout and design system that provides visual hierarchy and clear calls to action.

Additionally, pages should be optimized for different devices and screen sizes to ensure that they are accessible and usable for all users. This can be achieved by using responsive design techniques and testing the page on a variety of devices and browsers.

Anatomy

1. Header

- A. Home icon
- B. Title
- C. Button

2. Content

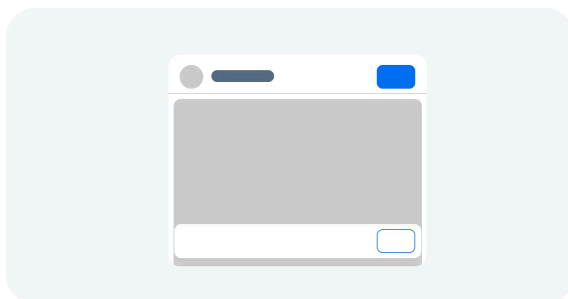

- ## 3. Footer (optional).
- The footer can float or be fixed at the bottom of the page.
- D. Button

Anatomy of a page

Types

The page can have a floating or fixed footer bar.

Behavior and Interaction

The page itself has no specific interactions. All interactions belong to the components within the page container and depend on the application use case.

For details, see the guidelines for the individual components, such as the [button](#).

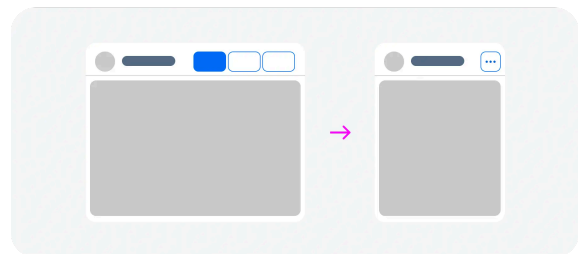

Example: Using a button in the header to navigate between pages

Responsive Behavior

The page offers considerable freedom and flexibility and the page header and the footer are designed to adapt automatically to small, medium, and large screen sizes.

- The title truncates if needed.
- The actions in the header and in the footer should stay as long as possible but when the space is not enough, they should transform to an overflow menu from right to left.
- If a priority is set to the actions, the highest priority button is the last to move to the overflow menu.
- It is also possible to assign one button never to move to the overflow menu.

Toolbar actions move to an overflow menu if there is not enough space

Letterboxing is used to limit the width of the content area to 1280 px. This prevents the app content from becoming too “stretched” on wide screens, and optimises readability. Letterboxing can be used if the use case requires it. However, most

entire screen, without letterboxing.

The page supports both cozy and compact mode.

Globalization and Localization

When designing an application, have in mind that this component also can be used with languages that use right-to-left direction for writing and reading. In this case the UI should be mirrored in order to be more convenient for the users to interact with it.
